Vascular Physiology And Pathophysiology

The physiologic property of hypoxic pulmonary vasoconstriction (HPV) allows the pulmonary vasculature to partially correct for this mismatch by shunting blood away from poorly ventilated alveoli. However, although HPV improves oxygenation acutely, when

Significance: This review considers how some systems controlling pulmonary vascular function are potentially regulated by redox processes to examine how and why conditions such as prolonged hypoxia, pathological mediators, and other factors promoting vascular remodeling contribute to the development of pulmonary hypertension (PH). Understanding the physiology and pathophysiology of the pulmonary circulation is critical in the diagnosis and management of PH. The pulmonary circulation is responsible for carrying deoxygenated blood from the heart to the lungs and returning oxygenated blood back to the heart for delivery to the systemic circulation.

Contribution of hypoxic pulmonary vasoconstriction (HPV) and vascular remodeling to the rise in pulmonary artery pressure (PAP) in chronic hypoxia. A, The initial rise in PAP in hypoxia is driven by HPV. The pressor response to hypoxia does not return to baseline on return to normoxia in

In the case of pulmonary hypertension, the pathophysiology of the disease is not always completely identified, but the two main mechanisms of pulmonary hypertension pathophysiology are increased pulmonary vascular resistance and increased pulmonary venous pressure. Increased Pulmonary Vascular Resistance As Pulmonary Hypertension

The role of vascular endothelial growth factor in the pathophysiology of PAH is controversial because the expression of vascular endothelial growth factor and its receptor are closely correlated with the formation of the plexiform lesion in human pulmonary hypertension, 76 and on the opposite, blockade of the vascular endothelial growth factor 2 receptor potentiates hypoxic pulmonary hypertension, 77 and cell-based gene transfer of vascular

The presence of pulmonary artery dilatation and subsequent reflex vasoconstriction; PE results in the elevation of the pulmonary vessel resistance as a consequence of not only mechanical obstruction of the capillary by the embolism, but also due to pulmonary vasoconstriction. Here, we review the knowledge regarding the components of MAMs according to their different functions and the specific roles of MAMs in cardiovascular physiology and pathophysiology, focusing on some highly prevalent cardiovascular diseases, including ischemia-reperfusion, diabetic cardiomyopathy, heart failure, pulmonary arterial hypertension and systemic vascular diseases.
